Introduction

4

- The rebound attack is a technique for hash functions cryptanalysis.
- Divide the block cipher E into 3: $E = E_{fw} \circ E_{in} \circ E_{bw}$
- Inbound phase (The meet in the middle phase) and Outbound phase
- Our Goal: Find a differential trail that will cause the input and output differentials to cancel each other

5

Terminology

1 byte = 8 bit

Each byte is represented by 2 hexadecimal digits

1 word = 4 byte = 32 bit

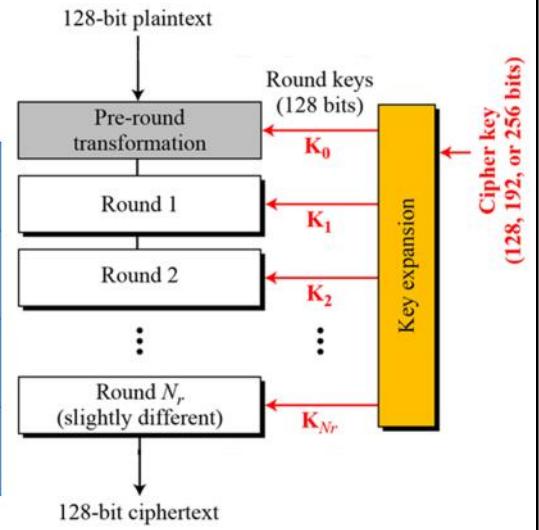

1 block = 4 words = 128 bit

Advanced Encryption Standard (AES)

6

- A private key symmetric block.

| Key Size (bits) | 128 | 192 | 256 |
|---|-----|-----|-----|
| Plain Text Block Size (bits) | 128 | 128 | 128 |
| Number of Rounds N_r | 10 | 12 | 14 |
| Round Key Size (bits) K_0, K_1, \dots, K_{N_r} | 128 | 128 | 128 |

Advanced Encryption Standard (AES) Structure Of Each Round

8

- Each round uses 4 transformations:
 - ▣ SubBytes
 - ▣ ShiftRows
 - ▣ MixColumns
 - ▣ Key Adding
- mixing transformation is missing from the last round.

Advanced Encryption Standard (AES)

Structure Of Each Round (SubBytes)

9

- 16 independent byte-to-byte transformations.
- We interpret the byte as two hexadecimal digits
- Use a transformation table (as S-box) to transform 8 bit to 8 bit.

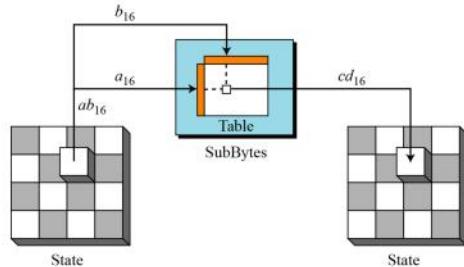

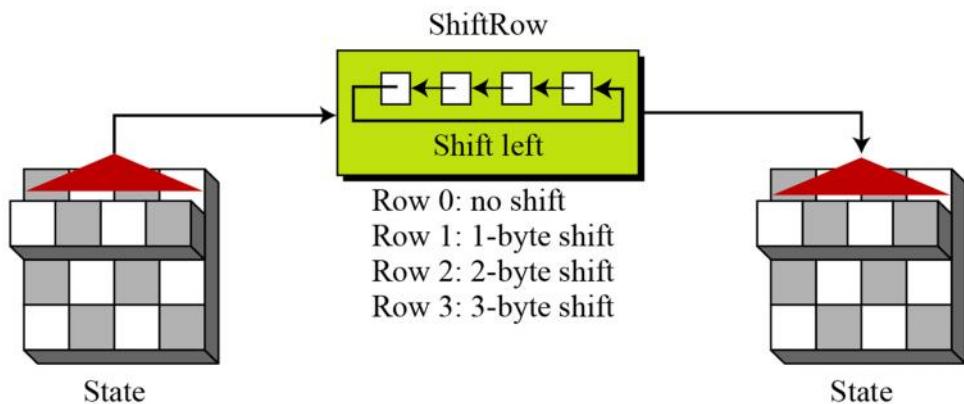

Table 7.1 SubBytes transformation table

| | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | A | B | C | D | E | F |
|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0 | 63 | 7C | 77 | 7B | FB | 6B | 6F | C5 | 30 | 03 | 67 | 2B | FE | D7 | AB | 76 |
| 1 | CA | 82 | C9 | 7D | FA | 59 | 47 | P0 | A0 | D4 | A2 | AF | 9C | A4 | 72 | C0 |
| 2 | B7 | FD | 93 | 26 | 3E | 3F | F7 | CC | 34 | A5 | E5 | F1 | 71 | D8 | 31 | 15 |
| 3 | 06 | C7 | 23 | C3 | 18 | 96 | 05 | 9A | 07 | 12 | 80 | B2 | EB | 27 | B2 | 75 |
| 4 | 09 | B3 | 2C | 1A | 1B | 6E | 5A | A0 | S2 | 3B | D6 | B3 | 29 | E3 | 2F | 84 |
| 5 | 53 | D1 | 00 | ED | 20 | FC | B1 | 5B | 6A | C9 | BE | 39 | 4A | 4C | 58 | CF |
| 6 | D0 | EF | AA | FB | 43 | 4D | 33 | 85 | 45 | P9 | 02 | 7F | 50 | 3C | 9F | A8 |

We interpret the byte as two hexadecimal digits.

Advanced Encryption Standard (AES) Structure Of Each Round (ShiftRows)

10

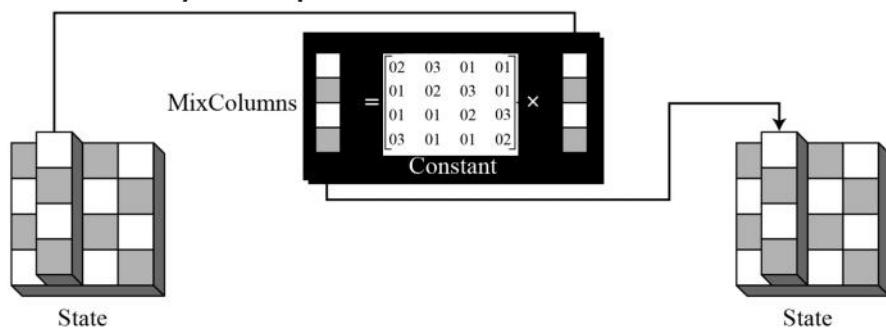

Advanced Encryption Standard (AES)

Structure Of Each Round (MixColumns)

11

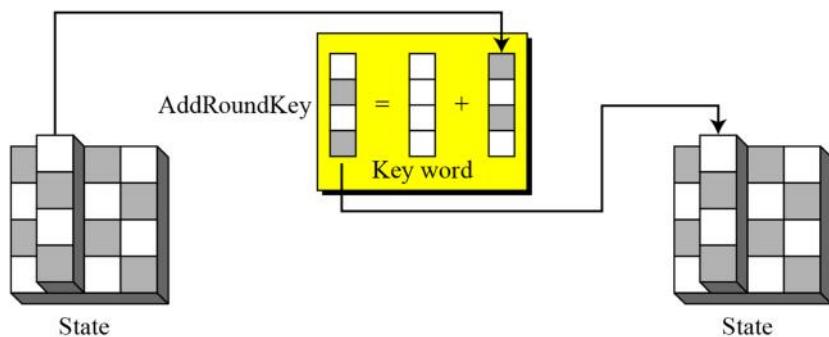

- Change bits inside a byte, based on the bits inside the neighboring bytes
- Transforms each column of the state to a new column by multiplication with a constant matrix.

Advanced Encryption Standard (AES) Structure Of Each Round (Add Round Key)

12

- The key is bitwise XORed to the state making the round function key dependent.

The Whirlpool Block Cipher

14

- first released in 2000 by Vincent Rijmen and Paulo S. L. M. Barreto.
Since then a few revisions have taken place.
- Free, Whirlpool's designers have promised never to patent
- Named after the Whirlpool washing machine – Not!

The Whirlpool Block Cipher

15

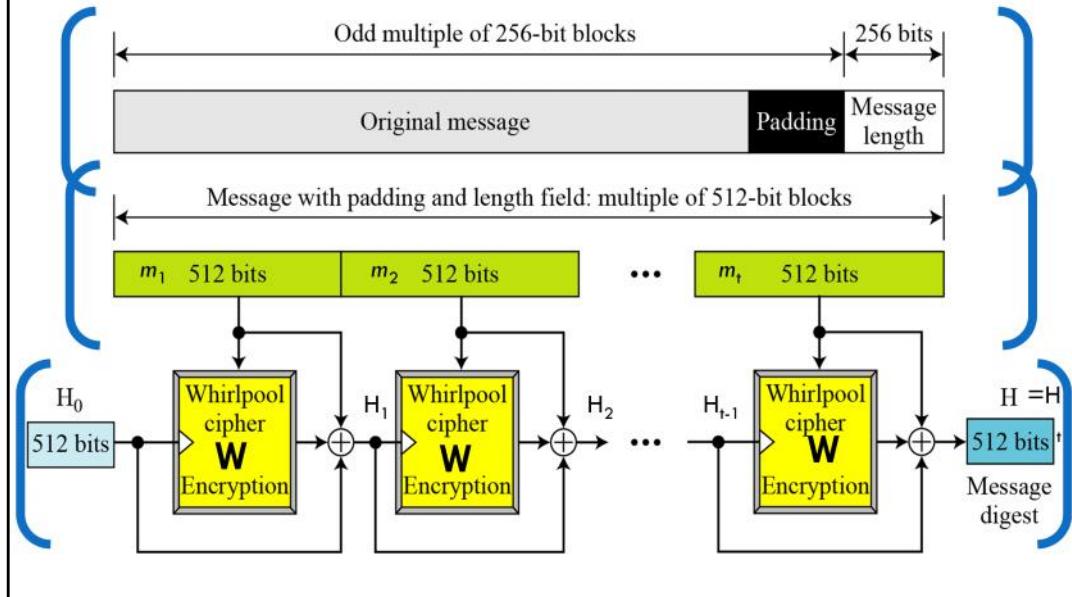

- first released in 2000 by Vincent Rijmen and Paulo S. L. M. Barreto. Since then a few revisions have taken place.
- Free, Whirlpool's designers have promised never to patent
- Named after the Whirlpool galaxy, the first one recognized to have spiral structure by William Parsons, third Earl of Rosse

The Whirlpool Block Cipher

The Miyaguchi-Preneel hashing scheme

16

This hash function is based on the the Merkle-Damgård scheme we already seen in class strengthening and the Miyaguchi-Preneel hashing scheme

The message is padded with a '1'-bit, then with a sequence of '0'-bits, and finally with the original length (in the form of a 256-bit integer value). The length after padding is a multiple of 512 bits.

The resulting message string is divided into a sequence of 512-bit blocks m_1, m_2, \dots, m_t which is then used to generate a sequence of intermediate hash values $H_0, H_1, H_2, \dots, H_t$. By definition, H_0 is a string of 512 '0'-bits.

To compute H_i , the block cipher **W** encrypts m_i using H_{i-1} as key, and XORs the resulting ciphertext with both H_{i-1} and m_i . Finally, the **WHIRLPOOL** message digest is H_t .

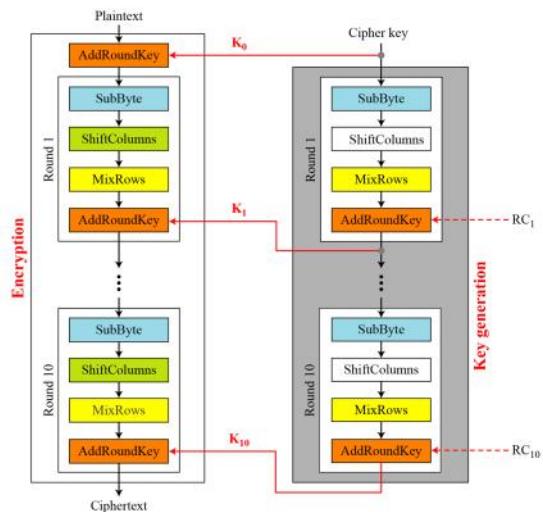

The encryption algorithm is described in the next slide.

The Whirlpool Block Cipher

What goes on inside the blocks?

17

- 10 rounds.
- The encryption algorithm involves the use of 4 transformations:
 - Substitute Bytes (SB)
 - Shift Columns (SC)
 - Mix Rows (MR)
 - Add Key (AK)

Whirlpool Cipher is very much like AES except minor differences:

1. The message length is 512 bit
2. Number of rounds is always 10
3. Key expansion is done in the round function and not in a dedicated algorithm
4. The S-Box in SybBytes is different
5. Instead of Shift Rows and Mix Columns we have Shift Columns and Mix Row

Table 1. Comparison of Whirlpool block cipher W and AES

| | W | AES |
|---------------------------|--|--|
| Block size (bits) | 512 | 128 |
| Key size (bits) | 512 | 128, 192, or 256 |
| Matrix orientation | input is mapped row-wise | Input is mapped column-wise |
| Number of rounds | 10 | 10, 12, or 14 |
| Key expansion | W round function | dedicated expansion algorithm |
| $GF(2^8)$ polynomial | $x^8 + x^4 + x^3 + x^2 + 1$ (011D) | $x^8 + x^4 + x^3 + x + 1$ (011B) |
| Origin of S-box | recursive structure | multiplicative inverse in $GF(2^8)$ plus affine transformation |
| Origin of round constants | successive entries of the S-box | elements 2^i of $GF(2^8)$ |
| Diffusion layer | right multiplication by 8×8 circulant MDS matrix (1, 1, 4, 1, 8, 5, 2, 9) - mix rows | left multiplication by 4×4 circulant MDS matrix (2, 3, 1, 1) - mix columns |
| Permutation | shift columns | shift rows |

The Whirlpool Block Cipher

Notations

20

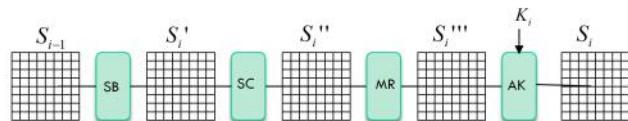

- The transformation applied on a state in the i round of Whirlpool will be marked

$$r_i = AK \circ MR \circ SC \circ SB$$

- The application of the S-Box on input x is marked $S(x)$

- The resulting stat of r_i will be marked as S_i .

- The state after SubBytes – S'_i ,
- The state after Shift Columns– S''_i ,
- The state after Mix Rows– S'''_i ,

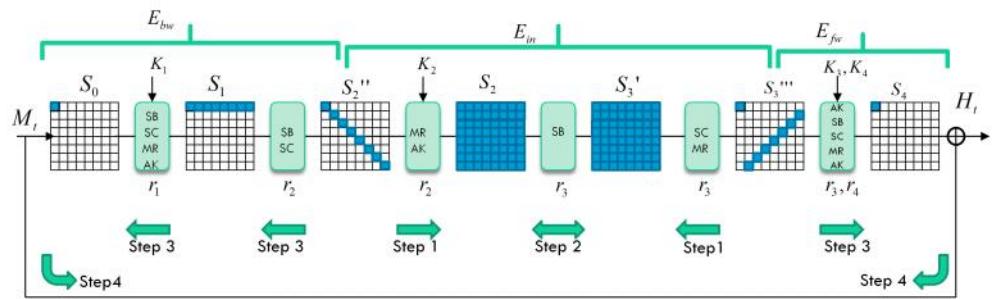

The Rebound Attack On Whirlpool

Overview

21

- The core of the attack is explained in reduced Whirlpool over 4.5 rounds
- Split the block to $E = E_{fw} \circ E_{in} \circ E_{bw}$
- Cause the differences in the first and last step to be equal and cancel each other.

First, we will give an overview of the attack strategy which is the basis for the attacks on 4.5, 5.5 and 7.5 rounds.

The main idea of the attacks is to use a 4-round differential trail, which has the following sequence of active S-boxes: $1 \rightarrow 8 \rightarrow 64 \rightarrow 8 \rightarrow 1$

Using the Rebound Attack we can cover the most expensive middle part using an efficient match-in-the-middle approach (inbound phase).

If the differences in the first and last step are identical, they cancel each other through the feed-forward. The result is a collision of the round-reduced compression function of Whirlpool.

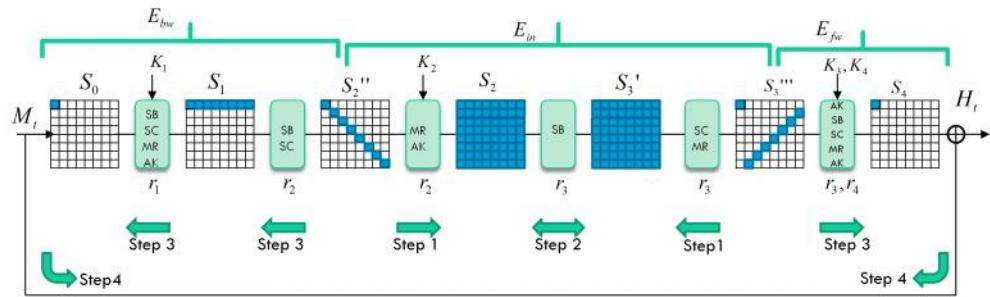

The Rebound Attack On Whirlpool

Overview

22

2 Phases

- Inbound phase (Step 1,2) expensive parts
 - Start with differences at rounds 2,3
 - Match in the middle at S-Box
- Outbound phase (Step 3,4) inexpensive parts
 - Probabilistic propagation of the MixRows of rounds 1 and 4
 - Match 1 byte difference

Inbound phase:

Step 1: start with 8-byte truncated differences at the MixRows layer of round r_2 and r_3 , and propagate forward and backward to the S-box layer of round r_3 .

Step 2: connect the input and output of the S-boxes of round r_3 to form the three middle states $8 \rightarrow 64 \rightarrow 8$ of the trail.

Outbound phase

Step 3: extend the trail both forward and backward to give the trail $1 \rightarrow 8 \rightarrow 64 \rightarrow 8 \rightarrow 1$ through MixRows in a probabilistic way.

Step 4: link the beginning and the end of the trail using the feed-forward of the hash function.

The Rebound Attack On Whirlpool

Collisions Attack On 4.5 Rounds

23

- Compute a 256×256 lookup table for each S-box differential.
 - About 50% of differentials exist

Pre-
Computation

- For S-Box S and 2 fixed differentials $(\Delta a, \Delta b)$
 - $\Delta a = x \oplus y$
 - $\Delta b = S(x) \oplus S(y)$
 - $\Pr[\Delta b = S(\Delta a)] \approx \frac{1}{2}$

Probabilities

The provability can be verified by enumerating through all 256×256 input/output pairs $(x; y)$ and $(S(x); S(y))$.

Note that for each possible S-box differential, we get at least the two symmetric values $(x; y)$ and $(y; x)$.

The table: The number of differentials and possible pairs $(x; y)$ for the Whirlpool and AES S-boxes. The first row shows the number of impossible differentials and the last row corresponds to the zero differential.

In the case of Whirlpool, we get for a small fraction of differentials even 8 possible pairs. This corresponds to the maximum probability distribution of the Whirlpool S-box, which is $8 \cdot 2^8 = 2^5$

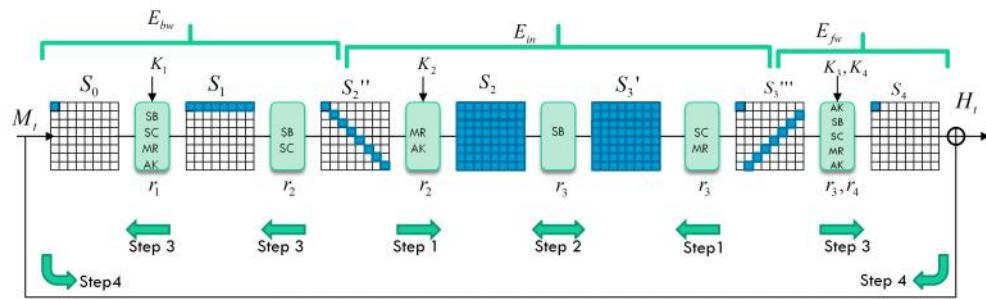

The Rebound Attack On Whirlpool

Collisions Attack On 4.5 Rounds

Step 1

24

- Choose random difference at S_2''
- Propagate forward to S_2
- Choose random difference at S_3'''
- Propagate backward S_3'

We start the attack by choosing a random difference with 8 active bytes of state S_2'' prior to the MixRows layer of round r_2 . Note that all active bytes have to be in the diagonal of state S_2'' . Then, the differences propagate forward to a full active state at the input of the next SubBytes layer (state S_3') with a probability of 1. Next, we start with another difference and 8 active bytes in state S_3''' after the MixRows transformation of round r_3 and propagate backwards. Again, the diagonal shape ensures that we get a full active state at the output of SubBytes of round r_3 .

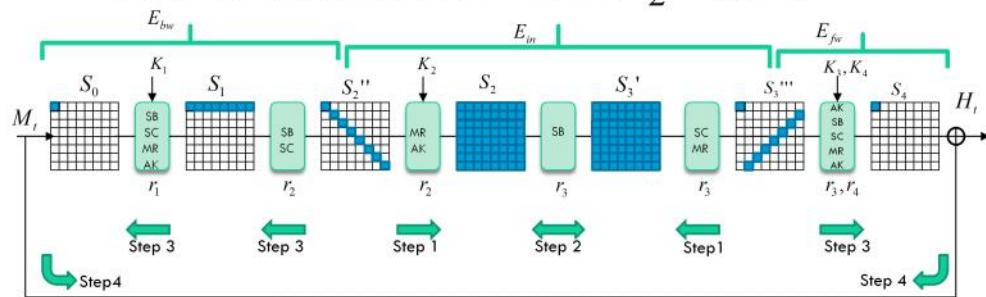

The Rebound Attack On Whirlpool

Collisions Attack On 4.5 Rounds

Step 2

25

- The match-in-the-middle step
- Look for suitable input\output difference using the pre-computed table.
 - We can find a match in 1 byte with the probability of $\frac{1}{2}$
 - We can find a match in 64 bytes with the probability of $\frac{1}{2^{64}}$
 - With the complexity of 2^{64} we get 2^{64} matches

We look for a matching input/output difference of the SubBytes layer of round r3 using the pre-computed S-box differential table.

Since we can find a match with a probability of 0.5 for each byte, we can find a differential for the whole active SubBytes layer with a probability of about 2^{64} . Hence, after repeating Step 1 of the attack about 2^{64} times, we expect to find a SubBytes differential for the whole state.

Each match gets 2-8 possibilities. Since we get at least two state values for each S-box match, we get about 2^{64} starting points for the outbound phase

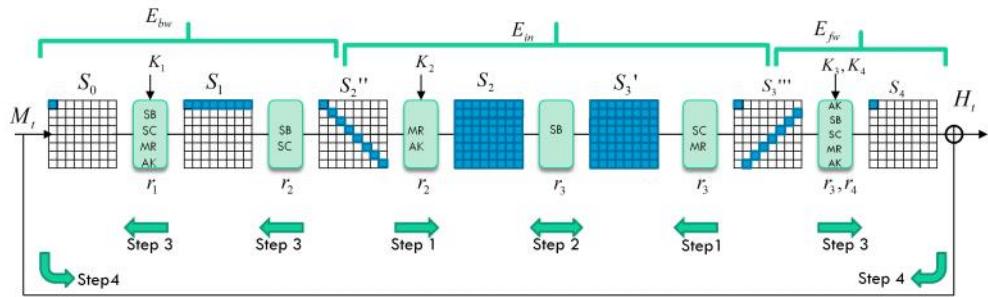

The Rebound Attack On Whirlpool

Collisions Attack On 4.5 Rounds

Step 3

26

- Extend the differential path backward and forward
- In the next SubBytes layer we get a truncated differential in 8 active bytes for each direction.
- Problem: need to propagate 8 bytes to 1.
 - This happens in the probability of $\frac{1}{2^{56}}$
- It has to be a specific byte needs in both directions
 - Repeat the inbound phase 2^{112} times.

In the outbound phase, we further extend the differential path backward and forward. By propagating the matching differences and state values through the next SubBytes layer, we get a truncated differential in 8 active bytes for each direction. Next, the truncated differentials need to follow a specific active byte pattern. In the case of the 4 round Whirlpool attack, the truncated differentials need to propagate from 8 to one active byte through the MixRows transformation, both in the backward and forward direction. The propagation of truncated differentials through the MixRows transformation is modeled in a probabilistic way. The transition from 8 active bytes to one active byte through the MixRows transformation has a probability of about 2^{-56} (7 bytes * 8 bits).

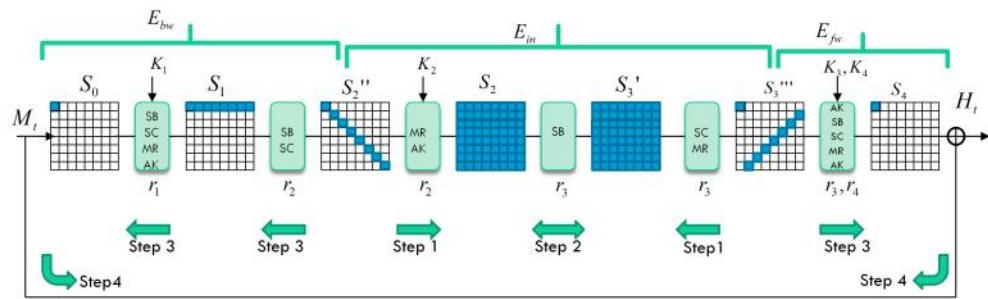

Note that we require a specific position of the single active byte to find a match in the feed-forward (Step 4). Since we need to fulfill one $8 \rightarrow 1$ transitions in the backward and forward direction, the probability of the outbound phase is $2^{-2*56} = 2^{-112}$. In other words, we have to repeat the inbound phase about 2^{112} times to generate 2^{112} starting points for the outbound phase of the attack.

The Rebound Attack On Whirlpool Collisions Attack On 4.5 Rounds

Step 4

27

- The value of the input and output difference has to match.
- This happens in probability $\frac{1}{2^8}$
- The complexity of finding a collision is $2^{112+8} = 2^{120}$

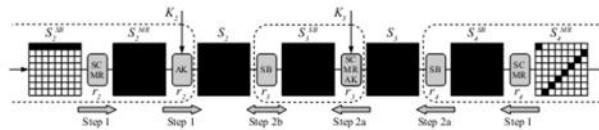

To construct a collision at the output of this 4 round compression function, the exact value of the input and output difference has to match. Since only one byte is active, this can be fulfilled with a probability of 2^{-8} . Hence, the complexity to find a collision for 4 rounds of Whirlpool is $2^{(112+8)}=2^{120}$. Note that we can add half of a round (SB,SC) at the end for free, since we are only interested in the number of active bytes. Remember that we can construct up to 2^{128} starting points in the inbound phase of the attack, hence we have enough degrees of freedom for the attack. Note that the values of the key schedule are not influenced.

The Rebound Attack On Whirlpool

Collisions Attack On 5.5 Rounds

28

- Add another full active state in the middle of the trail (inbound phase)
- Use the additional degree of freedom of the key scheduling to propagate the difference
- The outbound phase doesn't change

We can extend the collision attack on 4.5 rounds to a semi-free-start collision attack on 5.5 rounds of Whirlpool. The idea is to add another full active state in the middle of the trail. We use the additional degrees of freedom of the key schedule to fulfill the difference propagation through two full active S-box trans-formations.

Note that the outbound part of the attack stays the same and the new sequence of active S-boxes is: 1->8->64->64->8->1->1

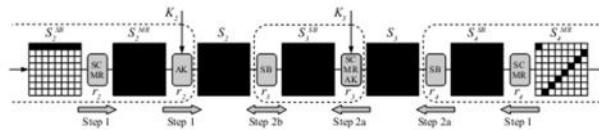

The Rebound Attack On Whirlpool

Collisions Attack On 5.5 Rounds

Step 1

29

- Choose initial differences with 8 active bytes at S_2'' and S_4'''
- Propagate differences forwards to S_2' and backwards to S_4'
- Find a matching SubBytes differential of 2 consecutive S-boxes

Again, we can choose from up to 2^{64} initial differences with 8 active bytes at state S_2'' and S_4''' and linearly propagate forward to S_2 and backward to S_4 until we hit the first S-box layer. Then, we need to find a matching SubBytes differential of two consecutive S-box layers in the match-in-the-middle phase

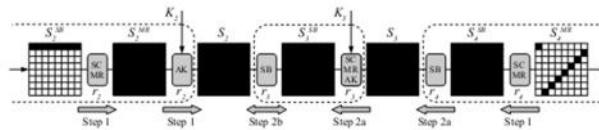

The Rebound Attack On Whirlpool

Collisions Attack On 5.5 Rounds

Step 2

30

- Select a value for S_4' (out of 2^{512} possible ones)
- Propagate towards S_3
- Propagate further back to state S_3' with 512 degrees of freedom of the key.

To pass the S-box of round r4 in the backward direction, we choose one of 2^{512} possible values for state S_4' .

This also determines the input values and differences of the SubBytes layer (state S_3).

Then, we propagate the difference further back to state S_3' with 512 degrees of freedom of the key.

That allows us to still assign arbitrary values to the state S_3' .

Hence, the correct difference propagation of the S-box in round r3 can be fulfilled by using these additional degrees of freedom to choose the state S_3' .

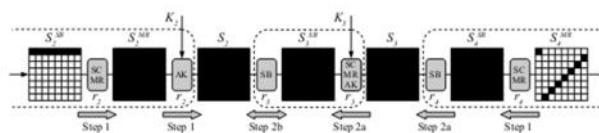

The complexity of the attack does not change and is determined by the 2^{120} trials of the outbound phase

The Rebound Attack On Whirlpool

Collisions Attack On 5.5 Rounds

31

- Since the outbound phase remains the same the complexity of the attack is still 2^{120}
- The main difference is that the round keys are determined by the inbound phase

The complexity of the attack does not change and is determined by the 2^{120} trials of the outbound phase

The outbound phase (Step 3 and Step 4) of the 5.5 round attack is equivalent to the 4.5 round case.

However, we cannot choose the round keys, and hence the chaining values, anymore since they are determined by the difference propagation of the S-box of round r3.

Therefore, this 5.5 round attack is only a semi-free-start collision attack on the hash function of Whirlpool.

Grøstl Block Cipher Overview

34

- An iterated hash function designed by a team of cryptographers from Denmark.

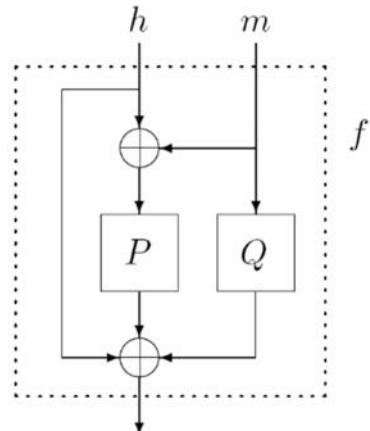

- Grøstl is a block cipher that is provably secure against differential cryptanalysis.

Grøstl Block Cipher

What goes on inside the blocks?

35

- The compression function is built from 2 fixed, large, different permutations.
- Very similar to Whirlpool
 - 10 rounds
 - Update an 8x8 state of 64 bytes

$$f(m, h) = P(m \oplus h) \oplus Q(m) \otimes h$$

The two permutations P and Q are constructed using the wide trail design strategy and borrow components from the AES. The design of the two permutations is very similar to the block cipher W used in Whirlpool instantiated with a fixed key input. Both permutations update an 8x8 state of 64 bytes in 10 rounds each.

Grøstl Block Cipher

What goes on inside the blocks?

36

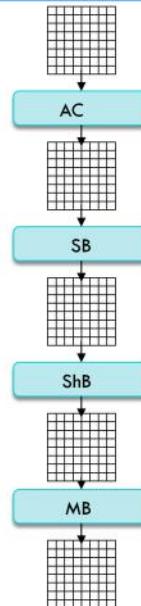

- The round transformation:

- AddRoundConstant (AC)
- SubBytes (SB)
- ShiftBytes (ShB)
- MixBytes (MB)

- In each round the state is updated as follows:

$$r_i = MB \circ ShB \circ SB \circ AC$$

Grøstl Block Cipher
What goes on inside the blocks?

AddRoundConstant (AC) adds different one-byte round constants to the 8x8 states of P and Q. (P & Q have different constants)
the non-linear layer SubBytes (SB) applies the AES S-Box to each byte of the state independently
The cyclical permutation ShiftBytes (ShB) rotates the bytes of row j left by j positions in P, Q
the linear diffusion layer MixBytes (MB) multiplies the state by a constant matrix
In the MixBytes transformation, each column in the matrix is transformed independently by multiplying each column in a constant 8x8 matrix,

Rebound Attack on Grøstl

Rebound Attack On 5 Rounds

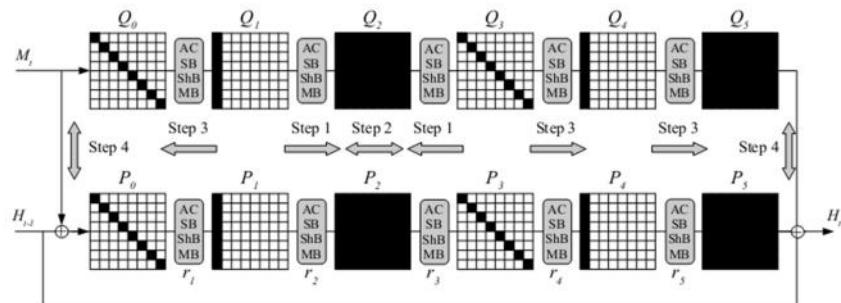

37

- Use the following differential trail

$$8 \xrightarrow{1} 8 \xrightarrow{2} 64 \xrightarrow{3} 8 \xrightarrow{4} 8 \xrightarrow{5} 64$$

- Semi free collisions 2^{120}

- Complexity of the attack

In the attack on 5 rounds, we use the following differential trail for both permutations:

$8 \rightarrow 8 \rightarrow 64 \rightarrow 8 \rightarrow 8 \rightarrow 64$

Do not allow diffs in H . all diffs are in m .

By using an equivalent differential trail in the second permutation one can find a collision for the compression function of Grøstl-256 reduced to 5 rounds with a complexity of 2^{64}

Step 1 and 2 the same as whirlpool only on 2 permutations

Require that the differential output of round 5 are equal

To prevent feed forwards to destroy the collision do not allow differences in H

Summary

39

- The idea of the rebound attack is to bypass the low probability parts of a hash function differential trail
- AES-based hash functions seem like natural candidates for such an attack.
- Can this attack be applied to a wider range of hash functions?

| hash function | rounds | computational complexity | memory requirements | type |
|---------------|--------|--------------------------|---------------------|--------------------------------|
| Whirlpool | 4.5/10 | 2^{120} | 2^{16} | collision |
| | 5.5/10 | 2^{120} | 2^{16} | semi-free-start collision |
| | 7.5/10 | 2^{128} | 2^{16} | semi-free-start near-collision |
| Grøstl-256 | 6/10 | 2^{120} | 2^{70} | semi-free-start collision |
